Dear Susan,

Please accept the accompanying Work Term Report entitled "Determining uses of JIRA and Confluence at OFI IBM."

This report is the result of work completed at the SOME GENEriC ORGANIZATION. During my first work

term as a University of Victoria student, I used charts and tables to display information about issue, complied documentation for critical applications in a wiki and researched addons to extend functionality. In the course of work, I gained exposure to a technical environment, and learned how software can integrate together.

Through the course of the term, I was given the opportunity to learn much agile software development, testing applications, and software products. I feel that this knowledge will be helpful in future work terms, and in my career.

I would like to thank my manager, MISTER MAN, for his patience and good judgement, as well as the RANDOM FOLK who were always willing to help. Sincerely,

David Li

Summary

Glossary

- **blockchain** A blockchain is a digitized, decentralized, public ledger of all cryptocurrency transactions. 1
- **Dapp** Decentralized Application have backend code running on a decentralized peer-topeer network and not controlled by a single entity. In a decentralized application transactions are versified through consensus of multiple users. 1, 3
- **Ethereum** an open software platform based on blockchain technology that enables developers to build and deploy decentralized applications 1, 3
- **HyperLedger** group of open-source blockchain technologies started by the Linux Foundation 1
- **HyperLedger Composer** permissioned blockchain that defines assets, business rules, and participants, and access controls for existing roles and types of transactions.
- smart contract computer program that directly controls transfer of digital currencies or assets under predefined conditions and used to automatic transactions on the blockchain. These transactions are trackable and irreservable. 1

1. Introduction

1.1. History of Cryptocurrency

Table 1	Timeline of Cryptocurrency
2008	Bitcoin White Paper
2009	Bitcoin Genesis Block
2013	1 BTC = \$ 31 USD
2013	Ethereum White Paper
2015	Ethereum Genesis Block
2015	HyperLedger starts
2017	Over 1000 different cryp-
	tocurrencies
2018	AWS Blockchain Templates

In 2008 bitcoin white paper [1] described a way to solve the double spending problem without a centralized body using blockchain. Although, the value of bitcoin (BTC) has grown exponentially, high computational and energy consumption in mining and slow performance [2]. Released in July 30, 2015, Ethereum, an opensource platform based on blockchain technology, distinguishes itself from bitcoin through faster transactions, unlimited processing capability for smart contracts, and its network is optimized to support Decentralized Application(DApp) [3].

1.2. Decentralized Applications

Blockchain technology is revolutionizing the internet by establishing trust in shared data. [4]. Additionally, transactions recorded on the blockchain are practically impossible to remove or change. A decentralized application, or DApp are deployed on peer to peer networks such as Ethereum or on the cloud ¹. A decentralized system (peer to peer) has many advantages over a conventional centralized network including no single points of failure, cheaper distribution (servers are expensive), faster upload speeds.

Types of Blockchains

- Public blockchains are large distributed networks that are run through a native token such as bitcoin or ether. Anyone can participate and the community maintains its open-source code. The two largest public blockchains are Ethereum and Bitcoin.
- Permissioned blockchains define role based access control for individuals in the network and uses native tokens. HyperLedger Composer, an open-source framework for permissioned blockchains, is used for smart contracts and for blockchain application development [5]. One use case is an accounting system that calculates payment, while hiding that information from unrelated organizations.

¹Amazon recently started offering blockchain templates on AWS. [3]

Private blockchains membership is tightly controlled and lacks a native token.
 Useful for consortiums with trusted associates and exchanging confidential information, however, less powerful because it is supported by limited private resources.

Public and Private Keys In a blockchain system, any key holder can use their private key to sign a piece of data. This results in a signature. In a Dapp, this can be used for:

- 1. Recovering the public key (ethereum account address) of the Author.
- 2. Verify if the raw data is the same as the one signed by Author using the public key.

1.3. Smart Contracts

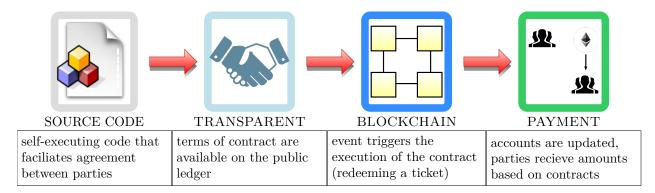

Figure 1: Illustrating how a smart contract works

2. Discussion

As shown in Figure 2 Dapp, a user's transactions on the application is publicly broadcasting to the blockchain. Implementing architecture for blockchain applications

adds an third layer to the standard client-server architecture ³. Disadvantages of blockchain data storage include difficult retrieving relevant information (without an abstraction layer, the entire blockchain or a single transaction is returned), users will experience latency before transactions are validated, ⁴

and writing to the blockchain is relatively expensive compared to traditional systems. Usage of interfaces such as the JSON RPC and/or cloud hosting solutions serve as a abstraction layer allowing databases to load publicly available data on the blockchain for more efficient user interactions with that information.

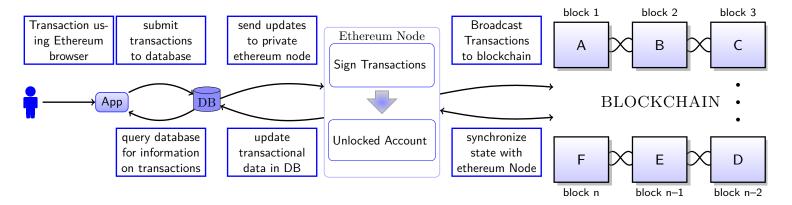

Figure 2: An example of server-blockchain architecture in a DAPP.

²Although, server-blockchain architecture with an abstraction layer resemble traditional applications, other approaches are available such as offline signing with a public node, and client-blockchain in serverless apps and leveraging cloud infrastructure.

³ Signing Transactions: One approach involves interacting with the JSON RPC interface of the Ethereum node from the application to perform all blockchain operations.

⁴For bitcoin, it takes 10 minutes before blocks of transactions are validated because of the mining process.

Criteria Centralized Public Permissioned Private
speed and latency
scale and volume
security and immutablity
transparency
